Abstract. In the present research, a time fractional inverse diffusion-wave problem of finding the inaccessible boundary value, by the input data at an interior point, is investigated. The numerical algorithm is based on the marching finite difference method. Because of ill-posedness of this inverse problem, we apply the mollification regularization technique to obtain a stable numerical solution. It is proven that the numerical scheme is stable and convergent. In the end, the performance of the proposed numerical approach is assessed by some test examples.

AMS (MOS) Subject Classification Codes: 35R30; 65M12; 35R25
Key Words: Time fractional diffusion-wave equation, Inverse problem, Mollification technique, Marching method, Stability analysis.

1. Introduction

In recent decades, employing differential and integral equations to model many phenomena in different branches of engineering and sciences, have been found more attention. Mathematical physics [2, 23], mechanical engineering [9, 12, 15, 24, 31], viscoelastic [3, 16], thermodynamics [14], complex materials [6, 11], heat transfer and distribution [5, 25], network synthesis [26] and mathematical Biosciences [7, 29] are some examples of
these disciplines. Some of these models are based on equations with fractional order operators. The fractional diffusion-wave equation is one of these equations that can be obtained from the generalization of the diffusion or wave equation of integer order. This equation is used to describe some anomalous diffusion processes [4, 16]. In some real situations, the boundary data related to the problem cannot be accessible. We only have some additional noisy measured data at an interior point of the domain of the problem. This type of problem is categorized as an inverse problem. The main difficulty in working on these problems is their ill-posedness, that is, some small noise in the input functions may be caused a large error in the solution of the problem [1, 8, 13, 19, 27, 30, 34]. Moreover, finding a numerical approximation for the fractional derivative is an ill-posed process, since the fractional derivative is defined by a nonlocal weak singular integration [21]. As a result, research works on inverse problems related to the time-fractional inverse diffusion-wave equation are very few.

Consider the following equation:

$$D_t^{\alpha} u(x, t) = u_{xx}(x, t) + f(x, t), \quad (x, t) \in \Omega := [0, 1] \times [0, 1],$$

with the initial and the boundary value conditions

$$u(x, 0) = \phi(x), \quad u_t(x, 0) = \psi(x), \quad x \in [0, 1],$$

$$u(0, t) = \varphi(t), \quad u(1, t) = \rho(t), \quad t \in [0, 1],$$

where $f(x, t)$ is the source term and $D_t^{\alpha} u(x, t)$ is the Caputo fractional derivative of order $1 < \alpha < 2$ defined as [22]:

$$D_t^{\alpha} u(x, t) = \frac{1}{\Gamma(2-\alpha)} \int_0^t \frac{\partial^2 u(x, s)}{\partial s^2} \frac{ds}{(t-s)^{\alpha-1}}, \quad \alpha \in (1, 2).$$

In this study, we are concerned with the inverse problem of approximating the unknown boundary condition $\rho(t)$, while the initial functions $\phi(x)$ and $\psi(x)$ and the boundary condition $\varphi(t)$ are considered as known functions. To determine the set of functions $(u, \rho)$ in the inverse problem (1.1)-(1.3), we need a supplementary condition. Here, the condition

$$u(\bar{x}, t) = \eta(t), \quad t \in [0, 1],$$

at an interior point $0 < \bar{x} < 1$ is used.

The paper consists of the following sections. In the next section, we separate the problem (1.1)-(1.4) into two direct and inverse subproblems, respectively in the domains $0 \leq x \leq \bar{x}$ and $\bar{x} \leq x \leq 1$. Afterwards, we apply an implicit finite difference method to obtain the numerical solution of the direct subproblem and a combination of the marching method along with the mollification method to solve the inverse subproblem. In Section 3, it is proven that the numerical procedure is stable and convergent. Finally, in Section 4, numerical examples are provided.

2. Numerical Procedure

2.1. Mollification regularization method

The time-fractional inverse problem with unknown boundary condition is sensitive to the noisy input data and is generally ill-posed [13]. In practice, we have only a perturbed approximation of the input function $\eta(t)$ in the condition (1.4). Thus, using an appropriate
regularization method is necessary to find a stable numerical solution. In this work, we employ the mollification technique. This method is a regularization procedure that stabilizes an ill-posed problem by restoring continuity subject to the data [17, 18, 20, 33]. It uses a convolution of the noisy input data and a smooth function with a parameter, to filter the high-frequency components of the noisy data.

Let $\delta > 0$ and $p > 0$ such that $p \delta < 0.5$. The $\delta$-mollification of an integrable function is based on convolution with the Gaussian kernel

$$
\rho_{\delta,p}(t) = \begin{cases} 
A_p \delta^{-1} \exp(-\frac{t^2}{2\delta^2}), & |t| \leq p\delta, \\
0, & |t| > p\delta.
\end{cases}
$$

where

$$A_p = \left( \int_{-p}^{p} \exp(-s^2)ds \right)^{-1}.
$$

The $\delta$-mollifier $\rho_{\delta,p}$ is a non-negative $C^\infty(-p\delta, p\delta)$ function vanishing outside $(-p\delta, p\delta)$ and satisfying

$$
\int_{-p\delta}^{p\delta} \rho_{\delta,p}(t) dt = 1. 
$$

Now, let $g(t)$ is an integrable function on $I = [0, 1]$ and $t \in I_\delta = [p\delta, 1 - p\delta]$. The $\delta$-mollification of $g$ is defined as

$$
\mathcal{J}_\delta g(t) = (\rho_{\delta,p} * g)(t) = \int_{t-p\delta}^{t+p\delta} \rho_{\delta,p}(t-s)g(s)ds.
$$

The parameter $\delta$ is specified by the generalized cross validation (GCV) criteria [20]. In the rest, we define the mollification of a discrete function.

Suppose $Z = \{1, 2, ..., m\}$, $K = \{t_j : j \in Z\} \subset I$ and $\Delta t = \sup_{j \in Z} (t_{j+1} - t_j)$, satisfying

$$
t_{j+1} - t_j > d > 0, \quad j \in Z,
$$

where $m$ is a positive integer and $d$ is a positive constant. Let $G = \{g(t_j) = g_j : j \in Z\}$ be a discrete function defined on $K$. We set

$$
s_j = \frac{1}{2}(t_j + t_{j+1}), \quad j \in Z.
$$

Now, the discrete $\delta$-mollification of $G$ is defined as:

$$
\mathcal{J}_\delta G(t) = \sum_{j=-\infty}^{\infty} \left( \int_{s_{j-1}}^{s_j} \rho_{\delta}(t-s)ds \right)g_j,
$$

and

$$
\mathcal{J}_\delta G(t_i) = \sum_{j=-\infty}^{\eta} \left( \int_{s_{j-1}}^{s_j} \rho_{\delta}(t_i-s)ds \right)g_j
$$

$$
= \sum_{j=-\eta}^{\eta} \left( \int_{s_{j-1}}^{s_j} \rho_{\delta}(-y)dy \right)g_{i+j}, \quad (2.6)
$$
where \( \eta = \left\lfloor \frac{p \delta}{\Delta t} \right\rfloor + 1 \). Subject to (2.5), we obtain
\[
\sum_{j=-\infty}^{\infty} \left( \int_{s_{j-1}}^{s_j} \rho \delta(t-s)ds \right) = \int_{-p\delta}^{p\delta} \rho \delta(s)ds = 1.
\]

**Theorem 2.1.** Let the functions \( g \) and \( g^\varepsilon \) are uniformly Lipschitz on \( \mathbb{R} \) and \( \| g - g^\varepsilon \|_\infty \leq \varepsilon \), then there exists a constant \( C \), independent of \( \delta \), such that
\[
\| J_\delta g^\varepsilon - g \|_\infty \leq C \delta + \varepsilon.
\]

**Theorem 2.2.** Let the functions \( g \) and \( g^\varepsilon \) are uniformly Lipschitz on \( \mathbb{R} \). Also, let \( G = \{ g_j : j \in \mathbb{Z} \} \) and \( G^\varepsilon = \{ g^\varepsilon_j : j \in \mathbb{Z} \} \) be the discrete versions of \( g \) and \( g^\varepsilon \), which are defined on \( K \), satisfying \( \| G - G^\varepsilon \|_\infty \leq \varepsilon \). Then
\[
\| D^2(J_\delta G)(t_j) - D^2(J_\delta G^\varepsilon)(t_j) \|_\infty \leq C \frac{\varepsilon}{\delta^2}, \quad j \in \mathbb{Z},
\]
where \( D^2 \) is second-order finite difference operator and \( C \) in the above relation is a constant, independent of \( \delta \).

The proofs of these theorems can be found in [20].

**Theorem 2.3.** Suppose \( G = \{ g_j : j \in \mathbb{Z} \} \) is the discrete version of \( g \), which is defined on \( K \) and let a differentiation operator \( D_\delta^2 \) be defined by the following rule:
\[
D_\delta^2(G) = D^2(J_\delta G)(t) \bigg|_K.
\]
Then, there exists a constant \( C \), independent of \( \delta \), such that
\[
\| D_\delta^2(G) \|_\infty \leq C \| G \|_\infty \frac{\delta}{\Delta t^2}.
\]

**Proof.** According to (2.6), for \( t = t_j \in K \), we have
\[
| D_\delta^2(G) | = \left| \sum_{j=-\infty}^{\infty} \left( \int_{s_{j-1}}^{s_j} \rho \delta(t + \Delta t - s) - 2 \rho \delta(t - s) + \rho \delta(t - \Delta t - s) \right) ds \right| g_j | \\
\leq \| G \|_\infty \sum_{j=-\infty}^{\infty} \int_{s_{j-1}}^{s_j} \left| \rho \delta(t + \Delta t - s) - 2 \rho \delta(t - s) + \rho \delta(t - \Delta t - s) \right| ds \\
= \| G \|_\infty \sum_{j=-\eta}^{\eta} \int_{s_{j-1}}^{s_j} \left| \rho \delta(\Delta t - y) - 2 \rho \delta(-y) + \rho \delta(-\Delta t - y) \right| dy,
\]
where \( \eta = \left\lfloor \frac{p \delta}{\Delta t} \right\rfloor + 1 \). So, we obtain
\[
| D_\delta^2(G) | \leq \| G \|_\infty \frac{\delta}{\Delta t^2} \sum_{j=-\eta}^{\eta} \int_{s_{j-1}}^{s_j} | d_\delta^\star(y) | dy,
\]
where
\[ d^\delta(y) = \rho_\delta(-(y - \Delta t)) - 2\rho_\delta(-y) + \rho_\delta(-(y + \Delta t)) \]
\[ = \int_0^{\Delta t} \int_{-\Delta t}^0 \rho_\delta''(-(y + \xi_1 + \xi_2))d\xi_1\xi_2, \]
and
\[ \rho_\delta''(x) = \frac{A_p}{\delta} \left( -\frac{2}{\delta^2} \exp(-\frac{x^2}{\delta^2}) + \frac{4x^2}{\delta^4} \exp(-\frac{x^2}{\delta^2}) \right). \]
Therefore, we have (see [20])
\[ |D_\delta^2(G)| \leq \frac{\|G\|_\infty}{(\Delta t)^2} \int_0^{\Delta t} \int_{-\Delta t}^0 \left( \sum_{j=-\epsilon}^{\epsilon} \int_{s_{j-1}}^{s_j} |\rho_\delta''(-(y + \xi_1 + \xi_2))|dy \right) d\xi_1\xi_2 \]
\[ = \frac{\|G\|_\infty}{(\Delta t)^2} \int_0^{\Delta t} \int_{-\Delta t}^0 \int_{-\epsilon}^{\epsilon} |\rho_\delta''(-(y + \xi_1 + \xi_2))|dy dy d\xi_1\xi_2 \leq \frac{C\|G\|_\infty}{\delta^2(\Delta t)^2}. \]

Suppose the exact function \( \eta \), in the additional condition (1.4), is not available, but a perturbed version \( \eta^\varepsilon \) is at hand. By applying the described method, we get \( \hat{\eta}(t) = J_\delta \eta^\varepsilon(t) \), where \( \hat{\eta} \) is the mollified version of \( \eta \) and \( \delta \) is called the radius of mollification. In the rest, we use \( \hat{\eta} \) in our numerical computations. Moreover, we will use the mollification technique to find a stable estimation of Caputo’s derivative.

2.2. The finite difference algorithm.

Now, we present a numerical scheme to solve the problem (1.1)-(1.4). For this purpose, we separate (1.1)-(1.4) into two subproblem. The first subproblem is a direct problem as:

\[ D_t^{(\alpha)} u(x,t) = u_{xx}(x,t) + f(x,t), \quad (x,t) \in [0, \bar{x}] \times [0,1], \quad (2.7) \]
\[ u(x,0) = \phi(x), \quad x \in [0, \bar{x}], \quad (2.8) \]
\[ u_t(x,0) = \psi(x), \quad x \in [0, \bar{x}], \quad (2.9) \]
\[ u(0,t) = \varphi(t), \quad t \in [0,1], \quad (2.10) \]
\[ u(\bar{x},t) = \eta(t), \quad t \in [0,1]. \quad (2.11) \]

because it has known initial and boundary conditions. Another subproblem is the following inverse problem:

\[ D_t^{(\alpha)} u(x,t) = u_{xx}(x,t) + f(x,t), \quad (x,t) \in [\bar{x},1] \times [0,1], \quad (2.12) \]
\[ u(x,0) = \phi(x), \quad x \in [\bar{x},1], \quad (2.13) \]
\[ u_t(x,0) = \psi(x), \quad x \in [\bar{x},1], \quad (2.14) \]
\[ u(\bar{x},t) = \eta(t), \quad t \in [0,1], \quad (2.15) \]
\[ u(1,t) = \rho(t), \quad t \in [0,1]. \quad (2.16) \]

Suppose
\[ x_i = ih, \quad i = 0, 1, ..., M, \]
\[ t_n = nk, \quad n = 0, 1, ..., N, \]
Applying the operator 
\[ J_\Omega = \left\{ \begin{array}{ll} 0, & M, \end{array} \right. \]
where A. Babaei, S. Banihashemi, A. Mohammadpour

Also, finite difference scheme for Eq. (2.19) as
\[ f_i^n = f(ih, nk), \quad \varphi^n = \varphi(nk), \quad \eta^n = \eta(nk), \quad \phi_i = \phi(ih), \quad \psi_i = \psi(ih), \]
and \( \bar{x} = sh \) where \( 1 \leq s \leq M - 1 \). To obtain an implicit finite difference formula for Eq. (2.7), we employ the discrete estimations to the time and space derivative terms which have been given in [32] as:
\[ u_t(x, t_n) = \frac{1}{k} (u_i^{n+1} - u_i^n) + O(k), \quad (2.17) \]
\[ \delta_{xx} u_i^n := u_{xx}(x, t_n) = \frac{1}{h^2} (u_{i-1}^n - 2u_i^n + u_{i+1}^n) + O(h^2). \quad (2.18) \]

where \( u_i^n = u(x_i, t_n) \).

The Riemann-Liouville fractional integral operator \( J_t \) of order \( \mu > 0 \) is defined as [22]:
\[ J_t^{(\mu)} f(x, t) = \frac{1}{\Gamma(\mu)} \int_0^t (t-s)^{\mu-1} f(x, s) ds. \]

Applying the operator \( J_t^{(\mu-1)} \) on the two sides of Eq. (2.7) results [10]:
\[ u_t(x, t) = \psi(x) + \frac{1}{\Gamma(\alpha-1)} \int_0^t \frac{\partial^2 u(x, s)}{\partial x^2} \frac{ds}{(t-s)^{\alpha-1}} + F(x, t), \quad (2.19) \]

where \( F(x, t) = J_t^{(\alpha-1)} f(x, t) \). Using Eqs. (2.17) and (2.18), we obtain the following finite difference scheme for Eq. (2.19) as
\[ u_i^{n+1} - u_i^n = k\psi_i + \gamma \sum_{j=0}^{n+1} \omega_j^{(\alpha)} \delta_{xx} u_i^{n-j+1} + kF_i^{n+1}, \quad (2.20) \]

where \( \gamma = \frac{k}{\tau^2}, \omega_0^{(\alpha)} = 1 \) and
\[ \omega_j^{(\alpha)} = \frac{(-1)^j \Gamma(2 - \alpha)}{\Gamma(j + 1) \Gamma(2 - \alpha - j)}, \quad j \geq 1. \]

Also,
\[ F_i^{n+1} = k^{\alpha-1} \sum_{j=0}^{n+1} \omega_j^{(\alpha)} f_i^{n-j+1} + O(k). \]

Now, we give a numerical scheme for solving the direct subproblem (2.7)-(2.11). By using Eq. (2.20), for \( i = 1, ..., s - 1 \) and \( n = 0, 1, ..., N - 1 \), we have
\[ -\gamma u_{i-1} + (1 + 2\gamma) u_i^1 - \gamma u_{i+1}^1 = u_i^0 + k\psi_i + kF_i^1, \quad (2.21) \]
for \( n = 0 \), and
\[ -\gamma u_{i-1}^{n+1} + (1 + 2\gamma) u_i^{n+1} - \gamma u_{i+1}^{n+1} = u_i^n + \gamma \sum_{j=1}^{n+1} \omega_j^{(\alpha)} \delta_{xx} u_i^{n-j+1} + k\psi_i + kF_i^{n+1}, \quad (2.22) \]
for \( n \geq 1 \), with the initial temperature distribution
\[ u_i^0 = \phi_i, \quad i = 0, 1, ..., s, \]
and
\[ u^n_0 = \varphi^n, \quad u^n_s = \eta^n, \quad n = 1, 2, ..., N. \]

Using Eqs. (2.21)-(2.22), for \( i = 1, ..., s - 1 \) and \( n = 0, 1, ..., N - 1 \), we obtain the following matrix form
\[ \mathbf{A} \mathbf{U}^1 = \mathbf{U}^0 + \Psi + \mathbf{F}^1, \quad (2.23) \]
in which
\[
\mathbf{A} = \begin{pmatrix}
1 + 2\gamma & -\gamma & 0 & 0 & \cdots & 0 \\
-\gamma & 1 + 2\gamma & -\gamma & 0 & \cdots & 0 \\
0 & -\gamma & 1 + 2\gamma & -\gamma & \cdots & 0 \\
\vdots & \vdots & \vdots & \vdots & \ddots & \vdots \\
0 & 0 & 0 & \cdots & -\gamma & 1 + 2\gamma & -\gamma \\
0 & 0 & 0 & \cdots & 0 & -\gamma & 1 + 2\gamma
\end{pmatrix}_{(s-1) \times (s-1)}
\]

\[
\mathbf{B} = \begin{pmatrix}
1 & -2 & 1 & 0 & 0 & \cdots & 0 \\
0 & 1 & -2 & 1 & 0 & \cdots & 0 \\
\vdots & \vdots & \vdots & \vdots & \vdots & \ddots & \vdots \\
0 & 0 & \cdots & 0 & 1 & -2 & 1
\end{pmatrix}_{(s-1) \times (s+1)}
\]

\[
\mathbf{U}^0 = (u^0_1, u^0_2, ..., u^0_{s-1})^t, \quad \mathbf{U}^1 = (u^1_1, u^1_2, ..., u^1_{s-1})^t, \quad \Psi = k(\psi_1, \psi_2, ..., \psi_{s-1})^t \text{ and} \]
\[
\mathbf{F}^1 = k(F^1_1, F^1_2, ..., F^1_{s-1})^t,
\]
where the superindex \( t \) denotes the transposition. Also, for \( n \geq 1 \), from (2.22) we have
\[ \mathbf{A} \mathbf{U}^{n+1} = \mathbf{U}^n + \gamma \sum_{j=1}^{n+1} \omega_j^{(\alpha)} \mathbf{B} \mathbf{U}^{n-j+1} + \Psi + \mathbf{F}^{n+1}, \quad (2.24) \]
in which
\[
\mathbf{U}^n = (u^n_1, u^n_2, ..., u^n_{s-1})^t,
\]
\[
\mathbf{U}^{n+1} = (u^{n+1}_1, u^{n+1}_2, ..., u^{n+1}_{s-1})^t,
\]
\[
\mathbf{U}^i = (u^i_0, u^i_1, ..., u^i_{s-1}, u^i_s)^t,
\]
\[ \Psi = k(\psi_1, \psi_2, ..., \psi_{s-1})^t \text{ and } \mathbf{F}^{n+1} = k(F^{n+1}_1, F^{n+1}_2, ..., F^{n+1}_{s-1})^t. \]

The linear systems (2.23) and (2.24) give the approximate solution of (2.7)-(2.11).

Now, we find the numerical solution of the inverse subproblem (2.12)-(2.16). To this end, we apply the proposed scheme for \( i = s+1, ..., M \) and \( n = 1, 2, ..., N \). Suppose \( v = \mathcal{J}_\delta u \) is the mollified version of \( u \) and the value of \( v(x,t) \) at \( (x_i,t_n) \) is indicated by \( U^n_i \). In addition, suppose
\[ W^n_i = v(x_i, n\delta), \quad Q^n_i = D^{(\alpha)}_t v(x_i, n\delta), \quad f^n_i = f(ih, nk), \quad \eta^n_i = \eta(nk). \]

Notice that
\[ U^n_s = \eta^n, \quad Q^n_s = D^{(\alpha)}_t (\eta^n), \quad n = 1, 2, ..., N, \]
and
\[ U^n_i = \phi_i, \quad i = s, s+1, ..., M. \]
It should be noted that \( u_{n-1}^n \) can be obtained from the solution of the direct subproblem. So, we can approximate \( v_n(x, t) \) at the node points as

\[
W^n_s = \frac{1}{h} (\bar{\eta}_n - u_{s-1}^n), \quad n = 1, 2, ..., N.
\]

Now, the approximate solution of (2.12)-(2.16) can be found by the finite difference marching scheme

\[
\begin{align*}
U_{i+1}^n &= U_i^n + hW_i^n, & (2.25) \\
W_{i+1}^n &= W_i^n + h(Q_i^n - f_i^n), & (2.26) \\
Q_{i+1}^n &= D_t^{(\alpha)}(\bar{J}_{i+1} U_{i+1}^n). & (2.27)
\end{align*}
\]

where \( i = s, ..., M - 1 \) and \( n = 1, 2, ..., N \).

In (2.27), let \( \bar{\theta}_i^n := \bar{J}_{i} U_{i}^n \) at each level \( i \) for \( n \in \{0, 1, ..., N\} \). The discrete computed fractional order derivative, denoted by \( D_t^{(\alpha)} \bar{\theta}_i^n \) in the grid points, will be as [28]

\[
D_t^{(\alpha)} \bar{\theta}_i^n = \frac{k^{-\alpha}}{\Gamma(3 - \alpha)} \sum_{r=0}^{i-1} d_{j,r} (\bar{\theta}_i^{r+2} - 2\bar{\theta}_i^{r+1} + \bar{\theta}_i^r) + O(k),
\]

where \( d_{j,r} = (j-r)^{2-\alpha} - (j-r-1)^{2-\alpha} \).

3. Stability and Convergence

In the present section, we prove that the finite difference scheme (2.25)-(2.27) for numerical solving of the inverse problem (2.12)-(2.16) is stable and convergent.

**Theorem 3.1.** (Stability of the marching algorithm) Suppose \( |U_i^n|, |W_i^n|, |Q_i^n| \) are maximum values of \( |U_i^n|, |W_i^n|, |Q_i^n| \), where \( n = 0, 1, ..., N \). For the marching scheme (2.25)-(2.27), there exist two constants \( \theta_1 \) and \( \theta_2 \), such that

\[
\max \left\{ |U_M^n|, |W_M^n|, |Q_M^n| \right\} \leq \theta_1 \max \left\{ |U_1^n|, |W_1^n|, |Q_1^n| \right\} + \theta_2.
\]

**Proof.** Let \( M_f = \max_{x,t \in [0,1]} \{ |f(x,t)| \} \). By using (2.25) and (2.26), we have

\[
|U_{i+1}^n| \leq (1 + h) \max \{ |U_i^n|, |W_i^n| \}, \\
|W_{i+1}^n| \leq (1 + h) \max \{ |W_i^n|, |Q_i^n| \} + hM_f.
\]

From (2.27) and Theorem 2.3, we obtain

\[
|Q_{i+1}^n| = |D_t^{(\alpha)}(\bar{J}_{i+1} U_{i+1}^n)| = \frac{1}{\Gamma(2 - \alpha)} \int_0^t \frac{D^2 (\bar{J}_{i+1} U_{i+1}^n)}{(t-s)^{\alpha-1}} ds \\
\leq \frac{1}{\Gamma(2 - \alpha)} \int_0^t \frac{C(||U_{i+1}^n||_\infty)}{(t-s)^{\alpha-1}} ds = \frac{C(nk)^{2-\alpha} ||U_{i+1}^n||_\infty}{\delta^2 k^2 \Gamma(3 - \alpha)}.
\]

Let \( \bar{\delta} = \min_{i} \{ \delta_i \} \). By applying (3.29), we have

\[
|Q_{i+1}^n| \leq \frac{C(nk)^{2-\alpha}(1 + h)}{\delta^2 k^2 \Gamma(3 - \alpha)} \max \{ |U_i^n|, |W_i^n| \}.
\]

Also, let

\[
\hat{C} = \max \left\{ 1, \frac{C(nk)^{2-\alpha}}{\delta^2 k^2 \Gamma(3 - \alpha)} \right\}.
\]
From (3.29)-(3.31), we obtain
\[
\max\{|U_{i+1}|, |W_{i+1}|, |Q_{i+1}|\} \leq (\hat{C} + h\hat{C}) \max\{|U_i|, |W_i|, |Q_i|\} + M_f.
\]
Iterating this inequality \(M - s\) times, we get
\[
\max\{|U_M|, |W_M|, |Q_M|\} \leq (\hat{C} + h\hat{C})^{M-s} \max\{|U_s|, |W_s|, |Q_s|\} + \tau M_f,
\]
where \(\tau = \sum_{i=0}^{M-s-1} (\hat{C} + h\hat{C})^i \). This inequality implies
\[
\max\{|U_M|, |W_M|, |Q_M|\} \leq \hat{C}^{M-s} \exp(1) \max\{|U_s|, |W_s|, |Q_s|\} + \tau M_f.
\]
Letting \(\theta_1 = \hat{C}^{M-s} \exp(1)\) and \(\theta_2 = \tau M_f\) complete the proof of stability. \(\square\)

**Theorem 3.2.** The finite difference marching scheme (2.25)-(2.27) is convergent.

**Proof.** Suppose \(i \in \{s+1, ..., M\}\) and \(n \in \{0, 1, ..., N\}\). First, we define the discrete error functions \(\Delta U_i^n = U_i^n - u(ih, nk)\) and \(\Delta W_i^n = W_i^n - u_x(ih, nk)\). By applying Theorem 2.2, we have
\[
|\Delta U_i^n - D^\alpha_t u(ih, nk)| = |D^\alpha_t (J_{\delta_x} U_i^n) - D^\alpha_t u(ih, nk) + O(k)| \\
= |D^\alpha_t (U_i^n - u(ih, nk)) + O(k)| \leq \frac{1}{\Gamma(2 - \alpha)} \int_0^{nk} \frac{C\varepsilon}{\delta_t^2 (nk - s)^{\alpha-1}} ds + O(k) \\
= \frac{C\varepsilon (nk)^{2-\alpha}}{\delta_t \Gamma(3 - \alpha)} + O(k) \leq \frac{C\varepsilon}{\delta_t \Gamma(3 - \alpha)} + O(k) = C_{\varepsilon} \frac{\varepsilon}{\delta_t^2} + O(k),
\]
where \(C_{\varepsilon} = \frac{C}{\Gamma(3 - \alpha)}\).

Expanding the exact solution \(u(x, t)\) by the Taylor series, we obtain
\[
u((i+1)h, nk) = u(ih, nk) + hu_x(ih, nk) + O(h^2), \quad (3.33)
\]
\[
u_x((i+1)h, nk) = u_x(ih, nk) + h(D^\alpha_t u(ih, nk) - f(ih, nk)) + O(h^2), \quad (3.34)
\]
From (2.25) and (3.33), we have
\[
\Delta U_{i+1}^n = U_{i+1}^n - u((i+1)h, nk) \\
= U_i^n + hW_i^n - u((i+1)h, nk) \\
= U_i^n + hW_i^n - u(ih, nk) - hu_x(ih, nk) + O(h^2) \\
= (U_i^n - u(ih, nk)) + h(W_i^n - u_x(ih, nk)) + O(h^2) \\
= \Delta U_i^n + h\Delta W_i^n + O(h^2).
\]

So, we result
\[
|\Delta U_{i+1}^n| \leq |\Delta U_i^n| + h|\Delta W_i^n| + O(h^2). \quad (3.35)
\]
By using (2.26), (3.32) and (3.34), we have
\[ \Delta W_{i+1}^n = \begin{array}{l}
W_{i+1}^n - u_x(i+1)h, nk \\
\quad = W_i^n + h(Q_i^n - f_i^n) - u_x(i+1)h, nk \\
\quad = W_i^n + h(Q_i^n - f_i^n) - u_x(ih, nk) - h(D_i^{(\alpha)}u(ih, nk) - f(ih, nk)) + O(h^2) \\
\quad = W_i^n - u_x(ih, nk) + h(Q_i^n - D_i^{(\alpha)}u(ih, nk)) + O(h^2) \\
\quad = \Delta W_i^n + hC, \quad \frac{\varepsilon}{\delta_i^2} + O(hk) + O(h^2).
\end{array} \]

So, we get
\[ |\Delta W_{i+1}^n| \leq |\Delta W_i^n| + hC, \quad \frac{\varepsilon}{\delta_i^2} + O(hk) + O(h^2). \quad (3.36) \]

Let \( |\Delta U_i| = \max_{0 \leq n \leq N} |\Delta U_i^n| \) and \( |\Delta W_i| = \max_{0 \leq n \leq N} |\Delta W_i^n| \). Thus, from (3.35), (3.36), we obtain
\[ |\Delta U_{i+1}| \leq |\Delta U_i| + h|\Delta W_i| + O(h^2), \]
\[ |\Delta W_{i+1}| \leq |\Delta W_i| + hC, \quad \frac{\varepsilon}{\delta_i^2} + O(hk) + O(h^2). \]

Let \( \delta = \min_i \{\delta_i\} \), hence
\[ |\Delta U_{i+1}| \leq (1+h) \max_i |\Delta U_i|, |\Delta W_i| + O(h^2), \]
\[ |\Delta W_{i+1}| \leq \max_i |\Delta W_i| + hC, \quad \frac{\varepsilon}{\delta_i^2} + O(hk) + O(h^2), \]

and
\[ \max_i \{|\Delta U_{i+1}|, |\Delta W_{i+1}|\} \leq (1+h) \max_i \{|\Delta U_i|, |\Delta W_i|\} + \Lambda, \]
where \( \Lambda = hC, \quad \frac{\varepsilon}{\delta_i^2} + O(hk) + O(h^2) \). Now, suppose \( \Delta_i = \max_i \{|\Delta U_i|, |\Delta W_i|\} \). Thus, we have
\[ \Delta_{i+1} \leq (1+h) \Delta_i + \Lambda, \]

and
\[ \Delta_M \leq (1+h) \Delta_{M-1} + \Lambda \]
\[ \leq (1+h)^2 \Delta_{M-2} + (1+h)\Lambda + \Lambda \]
\[ \leq ... \leq (1+h)^{M-s} \Delta_s + \tau \Lambda, \]
where \( \tau = \sum_{i=0}^{M-s-1} (1+h)^i \). Now, by using Theorem 2.1, for \( n \in \{0, 1, ..., N\} \), there exists constants \( C_n \) and \( D_n \), such that
\[ |\Delta U_s^n| = |U_s^n - u(sh, nk)| \leq C_n \delta + \varepsilon, \]
\[ |\Delta W_s^n| = |W_s^n - u_x(sh, nk)| \leq D_n \delta + \varepsilon. \]

Let \( C' = \max\{C_n, D_n\} \), then we have
\[ \Delta_s = \max\{|\Delta U_s^n|, |\Delta W_s^n|\} \leq C' \delta + \varepsilon, \]

and
\[ \Delta_M \leq \exp(1)(C' \delta + \varepsilon) + \tau \Lambda. \]
As a result, by choosing \( \delta = \delta(\varepsilon) \), when \( \varepsilon, h \) and \( k \) tend towards \( 0 \), \( \delta \) and \( \Lambda \) tend towards \( 0 \). Thus, \( \Delta M \) will tend to \( 0 \). It completes the proof.

\[ \text{4. Numerical implementation} \]

The present section is dedicated to investigating the ability of the introduced algorithm. To simulate the data for the inverse problem, some random noises are added to the data resulted from the function \( \eta(t) \), in the additional condition \((1.4)\). Suppose that \( \varepsilon \) is a noise level. For generating noisy data, the relation

\[ \hat{\eta} = \eta(0) + \varepsilon \times \text{rand}(i), \]

will be used, where \( \text{rand}(i) \) is a uniformly distributed random number in \([-1,1]\). Also, to demonstrate the accuracy of our method, by using the \( L^2 \)-norm, we define

\[ E_{L^2}(h,k) = \max_{1 \leq n \leq N} \| u^n - U^n \|. \]

We calculate the convergence order of the proposed method with the following formulas

\[ \text{Order}(h) = \log_{\frac{h_1}{h}} \left( \frac{E_{L^2}(h_1,k)}{E_{L^2}(h_2,k)} \right), \quad \text{Order}(k) = \log_{\frac{k_1}{k}} \left( \frac{E_{L^2}(h,k_1)}{E_{L^2}(h,k_2)} \right). \]

The computations are performed on a personal computer using a 2.20 GHz processor and the codes are written in Matlab R2014a.

Example 1. Consider Eq. \((1.1)\) with \( f(x,t) = -e^{x} (2t^\alpha + \frac{\pi \csc(\pi \alpha)}{\Gamma(-\alpha)}) \). Also, let \( \phi(x) = \psi(x) = 0, \varphi(t) = t^\alpha \) and \( \rho(t) = e^{t^\alpha} \). The exact solution of this problem is \( u(x,t) = t^\alpha e^{x} \).

Figure 1 shows the exact and the estimated solutions for \( \rho(t) \) with regularization and without regularization when \( \alpha = 1.5, x = 0.65, M = 200, N = 150 \) and \( \varepsilon = 1\%, 5\%, 10\%, 15\% \). Furthermore, Figure 2 shows the exact and the estimated solutions to \( \rho(t) \) for values \( \alpha = 1.2, 1.4, 1.6, 1.8 \) when \( x = 0.65, M = 200, N = 100 \) and \( \varepsilon = 1\%, 10\%, 20\% \).

Now, we test the errors in the sense of the \( L^2 \)-norm of the numerical solutions under various time and space steps. First, the temporal errors and convergence orders are investigated by fixing \( x = 0.5 \) and \( M = 100 \) and letting \( N \) vary. Table 1 presents the maximum \( L^2 \)-norm errors and convergence orders of the method. From which we can see that, in the presence of noise, the numerical errors are decreasing as the mesh is refined. Also, the convergence orders are more than 1. Next, we investigate the numerical accuracies of the method in space. The computational results, when \( N = 100 \), are listed in Table 2. It can be seen from the table that for various noise levels, by increasing the number of space steps, the errors are decreased. Also, the convergence orders become more than 1.5. So we can expect these values converge to 2 when the number of steps is increased. Those are in good agreement with the theoretical results.

Figure 3 shows the exact and numerical approximation of \( u(x,t) \) when \( \alpha = 1.5, x = 0.5, M = 200, N = 200 \) and \( \varepsilon = 10\% \). Finally, Figure 4 displays the absolute error function for the estimated solution when \( \varepsilon = 1\% \).
Figure 1. The function $\rho(t)$ and its numerical values without regularization and with regularization in Example 1 when $\alpha = 1.5$.

Figure 2. The function $\rho(t)$ and its numerical estimations in Example 1 for different values of $\alpha$ and $\varepsilon$ when $\bar{x} = 0.65$.

Example 2. In this example, we consider the inverse problem associated with the direct problem

$$D_t^{(\alpha)} u(x, t) = u_{xx}(x, t),$$

$$u(x, 0) = u_t(x, 0) = 0,$$

$$u(0, t) = 0,$$

$$u(1, t) = \begin{cases} t, & 0 \leq t \leq \frac{1}{2}, \\ 1 - t, & \frac{1}{2} < t \leq 1. \end{cases}$$
A numerical scheme to solve an inverse problem related to a time-fractional diffusion-wave equation

Figure 3. The exact and numerical solution for Example 1 when $\alpha = 1.5, \bar{x} = 0.5$ and $\varepsilon = 10\%$.

Figure 4. The absolute error function for numerical solution of Example 1 when $\alpha = 1.5, \bar{x} = 0.5$ and $\varepsilon = 1\%$. 
Here, we do not have the analytic solution of the problem. Thus, we will use the approximate solution of the direct problem, obtained by the numerical scheme proposed in Section 2, as an exact solution. Then, the additional data $\eta(t)$ will be found by using this supposed exact solution, although it contains some computational errors.

Figure 5 shows the function $\rho(t)$ and its estimations, with regularization and without regularization when $\alpha = 1.5$, $\bar{x} = 0.7$, $M = 200$, $N = 200$, and $\varepsilon = 1\%$, $5\%$, $10\%$, $15\%$. Also, Figure 6 shows the exact and the estimated solutions to $\rho(t)$ for several values of $\alpha = 1.3$, $1.6$ when $\bar{x} = 0.65$, $M = N = 200$ and $\varepsilon = 1\%$, $5\%$, $10\%$, $15\%$.

Now, we investigate the spatial and temporal errors and convergence orders. Let $\bar{x} = 0.5$ and $M = 100$. Table 3 presents errors and convergence orders for different time

Figure 6. The function exact $\rho(t)$ and its numerical approximations in Example 2 for several values of $\alpha$ and $\varepsilon$ when $\bar{x} = 0.65$.

5. Conclusion

In this work, a time-fractional inverse diffusion-wave problem for restoring an unknown boundary condition was investigated. To this aim, a numerical scheme based on the finite difference method was proposed. According to the ill-posedness of this type of inverse problems, the mollification technique was employed to compute the stabilized numerical solution. The numerical procedure was completely explained and it was proven that the presented method is stable and convergent. In the end, some test problems were surveyed.
A numerical scheme to solve an inverse problem related to a time-fractional diffusion-wave equation to show the ability and the accuracy of the mentioned algorithm. The obtained convergence orders confirm that the convergence speed of the presented method is good, even in the presence of the noise up to fifteen percent. Therefore, the results verify the accuracy and the stability of the method.

6. ACKNOWLEDGMENTS

The authors are thankful to the reviewers and the editor for suggestions to improve the presentation of the manuscript.
